Hyper-V Load-Balancing Algorithms - Altaro
We’ve had a long run of articles in this series that mostly looked at general networking technologies. Now we’re going to look at a technology that gets us closer to Hyper-V. Load-balancing algorithms are a feature of the network team, which can be used with any Windows Server installation, but is especially useful for balancing the traffic of several operating systems sharing a single

What is DNS-based load balancing? | DNS load balancing
Load balancing is the practice of distributing traffic across more than one server to improve performance and availability. Organizations use different forms of load
balancing to speed up both websites and private networks. Without load balancing, most Internet applications and websites would not handle traffic effectively or function correctly.

Nov 25, 2014 · Setting Server Weight for Balancing. In declarations of the backend servers, by default, each server is equally “weighted”. This assumes that each server can and should handle the same amount of load (taking into account the effects of the balancing algorithms). However, you can also set an alternative weight to servers during the declaration:

Oct 11, 2021 · IPVS is designed for load balancing and based on in-kernel hash tables. So you can achieve performance consistency in large number of Services from IPVS-based kube-proxy. Meanwhile, IPVS-based kube-proxy has more sophisticated load balancing algorithms (least conns, locality, weighted, persistence). API Object

The algorithms need to allow for the fact that presence of noise might skew the
measurements. In a typical power system, the State is quasi-static. The time constants are sufficiently fast so that system dynamics decay away quickly (with respect to measurement frequency). Load balancing via feeder reconfiguration is an essential application.
